- 1 Introduction
- 2 FDIR Analyses
- 3 Ongoing Activities
- 4 Tool Support

FDIR

- The FDIR (**Fault Detection, Isolation and Recovery**) sub-system is an essential block of safety-critical systems
- It runs **online**, in parallel with the system
- The FDIR block must be able to detect malfunctions, and carry out suitable reactions
- Needed to ensure **fault tolerance** of the system, and prevent the occurrence of safety hazards

Fault Detection, Isolation and Recovery

FDIR

- The FDIR (**Fault Detection, Isolation and Recovery**) sub-system is an essential block of safety-critical systems
- It runs **online**, in parallel with the system
- The FDIR block must be able to detect malfunctions, and carry out suitable reactions
- Needed to ensure **fault tolerance** of the system, and prevent the occurrence of safety hazards

Goals of FDIR

- **Fault detection**: identify malfunctions
- **Fault isolation**: precisely identify the fault responsible for a malfunction
- **Fault recovery**: recover after a fault has occurred, e.g. reconfiguring the system or switching operational mode

- 1 Introduction
- 2 FDIR Analyses**
- 3 Ongoing Activities
- 4 Tool Support

FDIR Effectiveness Analysis

- Evaluate the effectiveness of **an existing diagnoser**. It includes:
 - Fault Detection Analysis
 - Fault Isolation Analysis
 - Fault Recovery Analysis

FDIR Effectiveness Analysis

- Evaluate the effectiveness of **an existing diagnoser**. It includes:
 - Fault Detection Analysis
 - Fault Isolation Analysis
 - Fault Recovery Analysis

Diagnosability Analysis

- Check if **there exists a diagnoser** that can infer at run-time accurate and sufficient information on the behavior of the plant

FDIR Effectiveness Analysis

- Evaluate the effectiveness of **an existing diagnoser**. It includes:
 - Fault Detection Analysis
 - Fault Isolation Analysis
 - Fault Recovery Analysis

Diagnosability Analysis

- Check if **there exists a diagnoser** that can infer at run-time accurate and sufficient information on the behavior of the plant

Goals of FDIR Analyses

- Both analyses are carried out **offline** (on ground)
 - FDIR effectiveness analysis evaluates the capabilities of an implemented FDIR sub-system
 - Diagnosability analysis helps identifying if enough observables are available for building an FDIR sub-system

Diagnosis system

- **Plant** (Physical Device) in closed loop with a controller
- **Controller** is responsible for commanding actuators
- **Diagnosis system** tracks the hidden state of the plant over time

Diagnosis

Diagnosis system

- **Plant** (Physical Device) in closed loop with a controller
- **Controller** is responsible for commanding actuators
- **Diagnosis system** tracks the hidden state of the plant over time

Diagnosis

Diagnosis assumptions

- **Partial observability**: only a limited number of **observables** (e.g., sensors) can be monitored
- **Passive diagnosis**: diagnosis system cannot issue commands to the plant, in order to carry out diagnosis

Fault Detection

- Evaluates capabilities of an existing FDIR sub-system to **detect faults**
- Answers the question: “**Is it always possible to detect a fault?**”

Fault Detection

- Evaluates capabilities of an existing FDIR sub-system to **detect faults**
- Answers the question: “**Is it always possible to detect a fault?**”

Fault Detection in COMPASS

- It can be reduced to a **model checking problem**
- Given a fault F and an observable O : “Is it always the case that occurrence of F will eventually trigger O ?”
- Observable O is called a **detection means** for fault F
- COMPASS can synthesize all such observables, for any given fault.
- Detection means are **alarms** triggered by the FDIR sub-system

Fault Isolation

- Evaluates capabilities of an existing FDIR-sub-system to **identify faults**
- In general, when an anomaly is detected, it may be impossible to precisely identify the responsible fault
- Answers the question: “**Which faults are possible explanations for an event?**”
- **Perfect isolation**: only one fault is identified as possible explanation

Fault Isolation Analysis

Fault Isolation

- Evaluates capabilities of an existing FDIR-sub-system to **identify faults**
- In general, when an anomaly is detected, it may be impossible to precisely identify the responsible fault
- Answers the question: “**Which faults are possible explanations for an event?**”
- **Perfect isolation**: only one fault is identified as possible explanation

Fault Isolation in COMPASS

- It can be reduced to a **fault tree generation problem**
- Given a set of observable events O , generate a fault tree for each $o \in O$, representing the possible explanations for o
- Perfect isolation corresponds to a fault tree with only one MCS (of order 1)

Fault Recovery

- Evaluates capabilities of an existing FDIR sub-system to **recover from faults**
- Answers the question: “**Is it always possible to recover from a fault?**”

Fault Recovery

- Evaluates capabilities of an existing FDIR sub-system to **recover from faults**
- Answers the question: “**Is it always possible to recover from a fault?**”

Fault Recovery in COMPASS

- It can be reduced to a **model checking problem**
- A **recoverability property** can be specified by the user
- Fully general properties can be expressed
- E.g.: given a fault F and a condition P : “Is it always the case that whenever F occurs, eventually the system will satisfy condition P ?”

Plant

A **plant** is a tuple $P = \langle X, U, Y, \delta, \lambda \rangle$, where:

- X is a finite set, called the **state space**
- $X_0 \subseteq X$ is the set of **initial states**
- U is a finite set, called the **input space**
- Y is a finite set, called the **output space**
- $\delta \subseteq X \times U \times X$ is the **transition relation**
- $\lambda \subseteq X \times Y$ is the **observation relation**

Trace

A **trace** (feasible execution) of the plant, with a discrete number of time steps t , is as a sequence $\pi = \langle x^0, y^0, u^1, x^1, y^1, \dots, u^t, x^t, y^t \rangle$ such that:

- $x^0 \in X_0$
- $\delta(x_{i-1}, u_i, x_i)$ for $i = 1, \dots, t$
- $\lambda(x_i, y_i)$ for $i = 0, \dots, t$

Trace

A **trace** (feasible execution) of the plant, with a discrete number of time steps t , is as a sequence $\pi = \langle x^0, y^0, u^1, x^1, y^1, \dots, u^t, x^t, y^t \rangle$ such that:

- $x^0 \in X_0$
- $\delta(x_{i-1}, u_i, x_i)$ for $i = 1, \dots, t$
- $\lambda(x_i, y_i)$ for $i = 0, \dots, t$

Observable Trace

The observable part of a trace consists of the input and output signal:

$$obs(\pi) = \langle y^0, u^1, y^1, \dots, u^t, y^t \rangle$$

Diagnosability Analysis

Diagnosis condition

A **diagnosis condition** for a plant P is a pair of nonempty and disjoint sets of states $c_1, c_2 \subseteq X$, written $c_1 \perp c_2$

Diagnosability Analysis

Diagnosis condition

A **diagnosis condition** for a plant P is a pair of nonempty and disjoint sets of states $c_1, c_2 \subseteq X$, written $c_1 \perp c_2$

Critical Pair

A **critical pair** for diagnosis condition $c_1 \perp c_2$ and delay d , given plant P , is a pair of system traces π_1 and π_2 , both of length $t + d$, with the same observable traces w , such that $x_{\pi_1}^t \in c_1 \wedge x_{\pi_2}^t \in c_2$ holds

Critical Pair

Diagnosability Analysis

Diagnosis condition

A **diagnosis condition** for a plant P is a pair of nonempty and disjoint sets of states $c_1, c_2 \subseteq X$, written $c_1 \perp c_2$

Critical Pair

A **critical pair** for diagnosis condition $c_1 \perp c_2$ and delay d , given plant P , is a pair of system traces π_1 and π_2 , both of length $t + d$, with the same observable traces w , such that $x_{\pi_1}^t \in c_1 \wedge x_{\pi_2}^t \in c_2$ holds

Critical Pair

Diagnosability in COMPASS

- A plant is **diagnosable** if there exists no critical pair, that is, a pair of traces, one “good” and one “bad”, that are indistinguishable
- Diagnosability can be reduced to a model checking problem using the so-called **twin-plant** construction

- Diagnosability and Twin-Plant (Cimatti et. al, [IJCAI 2003](#))
- Synthesis of Observability Requirements (Bittner et. al, [AAAI 2012](#))
- Synthesis of FDIR (Alaña et. al, [DASIA 2012](#))

- 1 Introduction
- 2 FDIR Analyses
- 3 Ongoing Activities**
- 4 Tool Support

FDIR Synthesis

- New ESA study: **AUTOGEF**
- Automated synthesis of an FDIR sub-system starting from a set of FDIR requirements, including:
 - Architectural constraints (centralized vs distributed FDIR)
 - Detection, Isolation and Recovery requirements
 - Performance requirements

FDIR Development Lifecycle

- New ESA study: **FAME**
- Dedicated FDIR Development Methodology and V&V Process:
 - Formal specification and analysis techniques
 - Integration of inputs from Mission, System Analysis and Specification, System and Software Development
- Integrated framework implementing the methodology and process
- Based on COMPASS (and AUTOGEF)

Properties

- Sensor component fails
- Sensor component fails
- Sensor component fails
- A filter or a sensor fails
- Filters fail twice
- Sensor Failure
- Backup Sensor is used

Trace A
Compliant with diagnosability property.

Name	Step1	Step2	Step3	Step4
alarmF				
alarmS				
filters.filter1.#degrade				
filters.filter1.#die				
filters.filter1.error	OK	OK	OK	OK
filters.filter1.input	1	15	1	15
filters.filter1.mode				
filters.filter1.output	2	30	2	30
filters.filter1._resetEvent				
filters.filter2.#degrade				
filters.filter2.#die				
filters.filter2.error	OK	OK	OK	OK
filters.filter2.input	1	1	1	1
filters.filter2.mode				
filters.filter2.output	2	2	2	2

Trace B
Not compliant with diagnosability property.

Name	Step1	Step2	Step3	Step4
alarmF				
alarmS				
filters.filter1.#degrade				
filters.filter1.#die				
filters.filter1.error	OK	OK	OK	OK
filters.filter1.input	1	2	15	1
filters.filter1.mode				
filters.filter1.output	2	4	30	2
filters.filter1._resetEvent				
filters.filter2.#degrade				
filters.filter2.#die				
filters.filter2.error	OK	OK	OK	OK
filters.filter2.input	1	1	1	1
filters.filter2.mode				
filters.filter2.output	2	2	2	2

Run Check The property **Sensor component fails** was found to be **not diagnosable**.

FDIR Effectiveness

The screenshot shows the COMPASS Toolset interface for FDIR analysis. The window title is "COMPASS Toolset". The menu bar includes "File", "Edit", "View", "Activities", and "Help". The main toolbar contains "Model", "Properties", "Validation", "Correctness", "Performability", "Safety", and "FDIR".

The "Properties" panel on the left lists several properties with checkboxes:

- Sensor component fails
- Sensor component fails
- Sensor component fails
- A filter or a sensor fail
- Filters fail twice
- Sensor Failure
- Backup Sensor is Used

The main workspace is divided into four tabs: "Fault Detection Analysis", "Fault Isolation Analysis", "Fault Recovery Analysis", and "Diagnosability Analysis". The "Fault Detection Analysis" tab is active.

The active tab displays the text: "The given property produced a list observations". Below this text is a button labeled "Run Fault Detection".

Below the button is a "SAT bound:" label followed by a spinner control set to the value "10".

At the bottom of the workspace is an "Observation" panel containing the text "alarms".
